

# Metadata design

## What is the metadata?

The metadata is a simple `.csv` file that contains the information to (1) find and retrieve the data saved to a remote server and (2) to segment and transform the data to compare experimental conditions. I would recommend recording as many experimental variables as possible, just to be safe. Each row of the `.csv` file is an individual from the experiment. It is mandatory to have at least the following columns: 'machine\_name', 'region\_id', and 'date' with date in a YYYY-MM-DD format. Without these columns the data cannot be retrieved.

indiv.	machine_name	region_id	date	condition	sex	...	p
1	machine_001	1	2016-09-01	A	M	...	p <sub>1</sub>
2	machine_001	2	2016-09-01	B	M	...	p <sub>2</sub>
3	machine_002	1	2016-09-03	A	F	...	p <sub>3</sub>
...	...	...	...	...	...	...	...
n	machine <sub>n</sub>	region_id <sub>n</sub>	date <sub>n</sub>	condition <sub>n</sub>	sex <sub>n</sub>	...	p <sub>n</sub>

Mandatory

Optional

## Top tips.

- Make the metadata exhaustive. Record everything just encase you need information in the future.
- Once you've finished all your replicates, put them in the same `csv` file with a column "replicate" to identify them. It's easier than loading them separately.
- Make your metadata files straight away, as soon as you start your experiment. Time will erode the little details!
